A Tale of Two Wikipedia Data Projects: Link Enrichment, Document Classification

Wikipedia has grown to be a vast information resource that is not only useful for its readers, but also as a source of data to power analytical applications. In this talk, we present two of our recent projects that have done just that. The first project aims at improving Wikipedia inter-language links, by analyzing the link structure that connects related content across different languages of Wikipedia and generating new links. The second project has devised a method that uses the Wikipedia category information to derive sets of keywords, which are used to assist in classifying a collection of documents.
